21 **Abstract:** Cinchona alkaloids-derived sulfonamides and ester dimers containing chiral
22 hyperbranched polymers (HBPs) have been successfully synthesized and applied as
23 catalyst to asymmetric reactions. Several hyperbranched polymers derived from cinchona
24 alkaloids, incorporating sulfonamides and esters, have been synthesized through

1 Mizoroki-Heck coupling polymerization. These polymers were subsequently applied in
2 enantioselective Michael addition reactions. As these prepared polymers are not soluble
3 in a frequently used organic solvent, the polymers act as an efficient catalyst to the
4 enantioselective reaction of β -ketoesters to nitroolefins to give up to 99%
5 enantioselectivity with good yields. The insoluble property gives them extra space to
6 satisfy 'Green chemistry' requirement and is used up to several times without losing the
7 enantioselectivity.

8 **Key words:** Hyperbranched polymers (HBPs); sulfonamide; polymeric chiral
9 organocatalyst; Michael addition reaction.

10 1. Introduction

11 Cinchona alkaloid is a member of the Rubiaceae family and is derived from the bark of
12 various species of cinchona trees [1]. Cinchona alkaloids are the chemical substances with
13 the most vivid past. There are many instances of cinchona alkaloids being used as chiral
14 resolving agents today [2 - 5]. The key use of cinchona alkaloids in chemistry is to
15 expedite numerous enantioselective transformations in both homogeneous and
16 heterogeneous catalytic systems. Bredig and Fiske documented the first asymmetric
17 reaction utilizing a cinchona basis as early as 1912 [6,7]. The use of cinchona derivatives
18 in asymmetric catalysis has grown dramatically since the publication of many ground-
19 breaking studies. Now, it is understood that cinchona alkaloids and derivatives of them
20 are one of the most blatant organic chirality inducers, working to activate practically all
21 chemical processes in a highly stereoselective manner. The chiral induction and
22 discrimination mechanisms were explained by structural analysis of cinchona alkaloids
23 utilizing spectroscopic and computational techniques [8,9]. The main reason for the
24 widespread use of cinchona alkaloids by numerous researchers [10,11] in various

1 reactions, including hetero-[2 + 2] cycloadditions [12 - 14], phase transfer catalyzed
2 epoxidation [15 - 18], alkylation [19], conjugate additions [20,21], and phosphonylation
3 reactions of aldehydes [22,23], was the use of these compounds as chiral catalysts in
4 between the 1970s and 1980s. Cinchona alkaloids have a variety of functions that are
5 essential for producing chirality in asymmetric products, either on their own or in
6 chemically altered forms [24], because they contain both acidic and basic sites and these
7 behave as dual-functional chiral organocatalysts. A nucleophile and an electrophile can
8 both be activated and oriented by the hydroxyl moiety and tertiary amine, respectively
9 [25]. Cinchona alkaloids and their analogues are able to serve as catalysts that are chiral
10 in four distinct type of transformations, including the formation of carbon-carbon bonds,
11 carbon-oxygen bonds, carbon-hydrogen heteroatom bonds and also additional processes
12 including desymmetrization and hydrogenation. Bifunctional chiral catalysts, which can
13 concurrently interact with and activate both the reacting sites, are a reliable, efficient
14 technique to the stereoselective production of significant asymmetric molecules.
15 Sulfonamides, which can be produced from cinchona alkaloids, are among the most
16 significant and essential catalysts. In contrast to tertiary nitrogen of quinuclidine, which
17 in cinchona alkaloids may function as both a base and a hydrogen-bond acceptor, the
18 acidic NH part of sulfonamide is capable of functioning as a hydrogen-bond donor. Since,
19 the cinchona alkaloid-derived sulfonamides have both acidic and basic sites, they have
20 the unusual ability to keep a substrate in a certain orientation, creating a chiral
21 environment [26]. Additionally, C9 ester derivatives of cinchona alkaloids with free OH
22 [27], quinuclidine nitrogen [28 - 30], and a methoxy group adjacent to the C6' position of
23 the quinoline molecule extensively studied and used effectively in numerous asymmetric
24 processes [31 - 33]. The natural cinchona alkaloids in addition to alternate varieties like

1 bifunctional cinchona alkaloid derivatives are commonly utilized as a flexible source for
2 organocatalysts in the field of catalytic enantioselective chemical synthesis [34,35].
3 Along with cinchona alkaloids with the 6'-OH group [36], cinchona alkaloids with
4 thiourea moiety [37], and cinchona alkaloids along with 9-squaramide [38], dual-
5 functional cinchona alkaloid catalysts have also been found. Sulfonamide catalysts based
6 on cinchona alkaloids have been used to carry out asymmetric Michael-type reactions
7 successfully. For instance, According to Luo et al., the asymmetric Michael reaction of
8 1,3-dicarbonyl compounds with nitrostyrene demonstrated good catalytic activity for the
9 quinidine-derived sulfonamide. According to research by Itsuno et al., the Michael
10 addition reaction between ketoester and nitrostyrene exhibited greater stereoselectivity
11 when cinchonidine sulfonamides that served as bifunctional chiral organocatalysts [39].
12 Polymeric chiral organocatalysts are now used to great effect in the production of diverse
13 chiral building blocks. A chiral organocatalyst (such as cinchona squaramides,
14 sulfonamides, quaternary ammonium salt, cinchona ester, etc.) can be incorporated to
15 produce a polymer that can be used as a chiral polymeric organocatalyst in many
16 asymmetric reactions. Chiral polymers that include helical polymers, side-chain chiral
17 polymers, main-chain chiral polymers, chiral ligands with dendritic molecules, and
18 polymers with hyperbranched chirality. Polymeric chiral organocatalysts have drawn a
19 lot of interest in chemical synthesis of molecules that are optically active due to their ease
20 of removal from the reaction mixture and their capacity for multiple re-use. The design
21 of chiral polymeric catalysts for hyperbranched chiral polymer organocatalysts is the
22 primary focus of this work. Chiral catalysts were made by copolymerizing a variety of
23 chiral catalytic monomers with achiral monomers. A chiral catalyst is added to the main
24 structure of the polymer during polymer immobilization. In recent years, significant

1 advancements have been done in the chiral main-chain polymeric catalyst synthesis
2 process. In addition, several instances of polymer-immobilized catalysts have greater
3 enantioselectivities compare to the corresponding catalysts that has the low-molecular-
4 weight [40]. Different kinds of synthetic polymers, both organic and inorganic, have been
5 employed as supports for chiral catalysts, and it has been documented which polymer
6 network is best for each reaction [27]. As a substrate for the chiral catalyst, there are
7 various polymers such as cross-linked, branching, dendritic as well as linear shaped have
8 been used. A functional polymer with a chiral ligand can be polymerized to create a
9 polymer-support chiral organocatalyst, and different monomers can be utilized depending
10 on the kind of polymerization. Extremely branched three-dimensional (3D)
11 macromolecules are known as hyperbranched polymers (HBPs) [41]. Due to their
12 advantageous physical characteristics above those of their linear analogs, such as lower
13 inherent viscosity, a lower glass transition temperature, and a higher number of terminal
14 groups, hyperbranched polymers (HBPs) have garnered significant attention [41 - 46].
15 HBPs are therefore appropriate for a variety of uses, such as lubricants, coatings,
16 medication delivery systems, and also catalysts [47 - 51]. While HBPs are relatively
17 simple to manufacture in a single-step polymerization using the single-monomer
18 methodology (SMM) and double-monomer methodology (DMM) [52]. As our research
19 team has already established that the Mizoroki-Heck coupling process is trustworthy for
20 forming C-C bonds to produce chiral polymers from cinchona alkaloid derivatives, we
21 are concentrating on this coupling reaction in this article to synthesize HBPs [31, 53, 54].
22 The olefinic double bond of the sulfonamide dimer generated from cinchona alkaloid, the
23 cinchona ester dimer, and the halide of trifunctionalized aromatic iodide were combined
24 in the Mizoroki-Heck process to create chiral HBPs. In the asymmetric Michael Addition

1 reaction, we employed these hyperbranched polymers as chiral polymeric
2 organocatalysts.

3 **2. Result and discussion:**

4 **2.1 Synthesis of cinchona-derived sulfonamide and ester dimers and their corresponding** 5 **chiral hyperbranched polymers**

6
7 In this paper, we were mainly focusing to design HBPs based on cinchona sulfonamide
8 and cinchona ester dimers. These HBPs contain rigid catalytic centers that are
9 substantially more numerous, which may create a favorable microenvironment at the
10 catalytic sites and enable systematic manipulation of their catalytic characteristics. We
11 have synthesized various polymers of chiral organocatalyst by ion exchange
12 polymerization, etherification polymerization, neutralization polymerization and
13 quarternization polymerization. Sulfonyl chloride is very reactive towards amine, even in
14 mild reaction condition to give sulfonamide derivatives. So, sulfonamide dimers **3** except
15 **3e**, were designed and synthesized by the combination of C-9 aminated cinchona
16 alkaloids **1** [3(*R*),4(*S*),8(*S*),9(*S*)] and disulfonyl chloride **2** (Scheme 1) at rt. Only for 24
17 h reaction time with the excess amount of **1** (~ double amount of **2**), resulted pleasant
18 yield. C-9 aminated cinchona alkaloids **1** was synthesized from cinchona alkaloid **4**
19 [3(*R*),4(*S*),8(*S*),9(*R*)] having C-9 hydroxyl group by using the reported procedure [55,56].

1 **Scheme 1:** i) Synthesis of cinchona based sulfonamide dimers. ii) Demethylation of **3d** dimer
 2 by 1M BBr₃, dry CH₂Cl₂, Ar gas, -78°C to rt, 48h
 3 where C-6' OH carrying dimer **3e** was procured by demethylation of **3d** by using BBr₃
 4 (scheme 1) at -78 °C for 2 days. On the other hand, dimeric ester **6a** were resulted from
 5 C-9 hydroxyl cinchona alkaloids **4** and hexa acid chloride **5**. Cinchona ester dimer **6b**
 6 obtained from **6a** as **3e** prepared by demethylation (Scheme 2).

8 **Scheme 2:** i) Synthesis of ester dimers of cinchona. ii) Demethylation of **6a** dimer by 1M BBr₃,
 9 dry CH₂Cl₂, Ar gas, -78 °C to rt, 48h.
 10 Novel chiral hyperbranched polymers holding cinchona based sulfonamide and ester
 11 dimers were designed by accumulating of bifunctional dimers and trifunctional aromatic
 12 halides, **9**. The two C3-vinyl groups in the structure of cinchona dimers make it possible
 13 to carry out the polymerization process with aromatic iodides using a two-component
 14 type approach the Mizoroki-Heck coupling reaction is the most effective reaction among
 15 the numerous reactions that can proceed a C-C bond with a vinylic double bond [53, 54].
 16 In order to produce polymers, we therefore used the Mizoroki-Heck reaction between
 17 aromatic triiodides and divinyl compounds. These trifunctional aromatic iodide
 18 compound **9a** and **9b** were prepared from trihydroxybenzene and tris phenol with
 19 iodobenzoylchloride **8** respectively at room temperature (Scheme 3) [57, 58]. Tris phenol
 20 and iodobenzylbromide **10** were used to make another class of trifunctional compounds
 21 **9c** which has three iodophenyl groups. (Scheme 3) [57]. Repeated MH reactions take

1 place in the presence of a catalyst, Pd(OAc)₂ when these triiodo aromatic compounds **9**
 2 are combined with cinchona dimers **3** or **6**, and the resulting chiral hyperbranched
 3 polymers (Scheme 4) are produced with a high yield (up to 93%, entry 6). One reaction
 4 route has been shown in (Scheme 4).

5

6

Scheme 3: Different synthetic route of trifunctional aromatic iodides.

Scheme 4: Synthesis of chiral HBP **P2-3b**.

The reaction mixture became precipitated in ether after polymerization, and then washed with ether and water to yield the polymer powder. The desired polymers of entry **1-5** were prepared by the Mizoroki-Heck polymerization using cinchona alkaloids based sulfonamide dimers **3** and the entry **8-9** resulting from cinchona ester dimers **6** with triiodide **9a**, where entry **6-7** are procured from different type of trifunctional aromatic iodide **9b** and **9c** with sulfonamide dimers **3b**. The HBPs that we obtained were soluble in DMF and DMSO, except **P6-3b** and **P7-3b** those were dissolved minimally. But all polymers were slightly dissolved in other prevalently used organic solvents, for instance, dichloromethane, methanol, diethyl ether, ethyl acetate, THF, hexane as well as acetone. The outcomes of the MH polymerization of aromatic triiodides and cinchona dimers are shown in Table 1. In every cases, chiral HBPs gives higher molecular weight of around over 10,000 was found. But we couldn't take molecular weight for polymer **P6-3b** and **P7-3b** due to poor solubility in DMF.

Table 1: Synthesis of chiral hyperbranched polymers of different cinchona dimers and trifunctional aromatic iodides by applying Mizoroki-Heck polymerization.

2.2 Catalytic activity of cinchona alkaloid derived dimers and Hyperbranched polymers (HBPs):

We have selected the asymmetric Michael addition of methyl 2-oxocyclopentanecarboxylate **11** to *trans*-β-nitrostyrene **12** as the model reaction (Scheme **5**) to examine the catalyst's function of the cinchona based chiral Hyperbranched polymers. Initially, we took a look for dimeric low-molecular-weight catalysts in the enantioselective Michael addition reaction in CH₂Cl₂ at room temperature, reaction proceeded smoothly and got excellent enantioselectivities up to 99% with preferable yield

1 (up to 96%) except **6a** which gave only 44% ee (Table 2 entry 6). Table 2 provides a
 2 summary of the results of the asymmetric Michael reaction of **11** and **12** using low-
 3 molecular dimeric catalysts. We are encouraged by these results to use the corresponding
 4 sulfonamide polymers as a catalyst by applying the same procedure. Then, HBPs of the
 5 respective dimers have been synthesized as polymeric organocatalysts and employed for
 6 the same reaction. In the first instance, we trialled hyperbranched polymeric catalyst **P1-**
 7 **3a**.

8 **Table 2:** Asymmetric Michael addition^a of β -ketoesters (**11**) with *trans*- β -nitrostyrene (**12**) using
 9 various dimers.

Entry	Catalysts	Reaction time [h]	Yield ^b [%]	<i>dr</i> ^c [%]	<i>ee</i> ^c [%]
1	3a	24	93	7.6:1	99
2	3b	24	96	15:1	99
3	3c	28	79	7.9:1	98
4	3d	42	62	4.7:1	99
5	3e	3	92	10:1	97
6	6a	32	72	0.6:1	44
7	6b	20	94	5.3:1	99

10 ^aAt room temperature, asymmetric reactions involving **11** (0.50 mmol), **12** (0.55 mmol), and the dimeric
 11 catalyst (5 mol%) were conducted in 2.5 mL of CH₂Cl₂. ^bIsolated yield after purification by the column
 12 chromatography ^cEnantioselectivity (ee), as assessed by HPLC (flow rate: 1.0 mL/min on chiral cel OD-
 13 H).

14 Although it was insoluble in CH₂Cl₂ gives heterogeneous mixture, the asymmetric
 15 Michael addition of *trans*-nitrostyrene **12** and methyl 2-oxocyclopentanecarboxylate **11**
 16 progressed without any cumbersome

1 **11** **12** **13**

2 Scheme 5: Asymmetric Michael addition^a of β -ketoesters (**11**) with *trans*- β -nitrostyrene (**12**).

3 at the room temperature to provide corresponding asymmetric product up to 99% ee with

4 96% yield. However, a higher reaction time was demanded owing to heterogeneous

5 system for polymeric catalysts. It was almost similar result compared with previously

6 reported cinchona based sulfonamide main chain type linear polymer [58]. In this case,

7 half (5 mol %) catalyst loading was required compared to linear polymers.

8 **Table 3:** Asymmetric Michael addition^a of β -ketoesters (**11**) with *trans*- β -nitrostyrene (**12**) using

9 different HBPs.

1.	Entry	Catalysts	Reaction time [h]	Yield ^b [%]	<i>d</i> ^r [%]	<i>ee</i> ^c [%]
	1	P1-3a	36	96	4.5:1	99
	2	P2-3b	24	84	8:1	>99
	3	P3-3c	30	86	6.4:1	98
	4	P4-3d	36	81	6.4:1	98
	5	P5-3e	24	75	5.5:1	99
	6	P6-3b	36	63	10.5:1	94
	7	P7-3b	36	67	11.3:1	96
	8	P8-6a	24	59	1.1:1	64
	9	P9-6b	24	73	5.9:1	>99

10 ^aAt room temperature, asymmetric reactions involving **11** (0.50 mmol), **12** (0.55 mmol), and the

11 polymeric catalyst (5 mol%) were conducted in 2.5 mL of CH₂Cl₂. ^bIsolated yield after purification by the

12 column chromatography ^cEnantioselectivity (ee), as assessed by HPLC (flow rate: 1.0 mL/min on chiral

13 cel OD-H).

14

15 Shorter reaction time needed when **P2-3b** more flexible structure than **P1-3a** was used as

16 catalyst, the chiral product **13** obtained with nearly perfect enantioselectivity of the major

1 diastereomer (over 99%) within 24 hours (Table 3 entry 2). Though it gave better
2 enantioselectivity comparing with corresponding dimer, but diastereoselectivity
3 somewhat diminished. A competent performance was executed by chiral HBPs in
4 particular asymmetric reaction might be because of creating microenvironment in chiral
5 polymer network. Other polymers also demonstrated splendid enantioselectivity (94 to
6 99%) except for the result obtained by using **P8-6a** (Table 3 entry 8). It was derived from
7 quinine ester dimer **6a** having C6' methoxyl group which gave lower enantioselectivity
8 for the selected model Michael reaction due to lack of acidic proton. Poor
9 enantioselectivity also displayed by dimeric catalyst **6a** dimer. The enantioselective
10 Michael addition reaction proceeded under the same conditions when the chiral
11 hyperbranched polyester **P9-6b** with C6'-OH was used as a catalyst, yielding **13** with
12 significantly better enantioselectivity (99% ee, Table 3 entry 9). Compared with the result
13 obtained by using corresponding dimer catalyst **6b**, **P9-6b** catalyst took somewhat longer
14 time because of heterogeneous condition. Changing trifunctional aromatic compound **9b**
15 and **9c** instead of **9a**, lower enantioselectivity and yield obtained with longer reaction time
16 for HBPs **P6-3b** and **P7-3b** (Table 3 entry 6 & 7) compared with **P2-3b** (Table 3 entry
17 2). Then we screened the influence of solvents on the catalytic activity by using HBP **P2-**
18 **3b**. The results of the Michael addition reaction for **P2-3b** catalyst have been recapitulated
19 in Table 4 with the diversity of solvents. The reactions were highly enantioselective above
20 95% ee for all the selected solvents with good yields. But in case of ethyl acetate only
21 27% yield obtained with 97% ee (entry 4, table 4). Though acetonitrile, THF, acetone
22 gave somewhat lower yield (entry 2, 6, 7 table 4) compared with dichloromethane, but
23 still maintaining pleasant enantioselectivity. The most effective solvent for this model

1 Michael reaction is CH_2Cl_2 , with over 99% ee and 84% yield, was determined after
 2 investigating the impact of the solvent (entry 1, table 4).

3 **Table 4:** Asymmetric Michael addition^a of β -ketoesters **11** to *trans*- β -nitrostyrene **12** using
 4 hyperbranched polymeric catalyst **P2-3b** in different solvents.
 5

Entry	Solvent	Yield ^b [%]	<i>dr</i> ^c [%]	<i>ee</i> ^c [%]

6	THF	52	6.6:1	96
7	CH_3CN	55	4.9:1	98

6 ^aAt room temperature, asymmetric reactions involving **11** (0.50 mmol), **12** (0.55 mmol), and the
 7 polymeric catalyst (5 mol%) were conducted in 2.5 mL of CH_2Cl_2 . ^bIsolated yield after purification by the
 8 column chromatography ^cEnantioselectivity (ee), as assessed by HPLC (flow rate: 1.0 mL/min on chiral
 9 cel OD-H).

10

11 **Scheme 6:** Michael addition reaction of various Michael donors and acceptors by using polymer
 12 **P2-3b** as catalyst.

1 Afterward, we applied chiral HBP **P2-3b** to monitor asymmetric Michael addition
 2 reaction by changing the Michael acceptor substituents as well as Michael donors
 3 (Scheme 6), and the results are summarized in Table 5. Higher enantioselectivity was
 4 observed by using methyl 2-oxocyclopentanecarboxylate **11** and ethyl 2-
 5 oxocyclopentanecarboxylate **14** as Michael donor for all of the reactions (entries 1-4,
 6 Table 5) except entry 2.

7
 8 **Table 5:** Enantioselective Michael addition^a reaction resulted from the combination of different
 9 donors and acceptors using polymeric catalyst, **P2-3b**.
 10

Entry	Michael donor	Michael acceptor	Product	Reaction time [h]	Yield ^b [%]	dr ^c [%]	ee ^c [%]
1	14	12	18	42	77	14.4:1	92
2	11	15	19	48	87	9.3:1	73
3	11	16	20	46	82	1.7:1	>99
4	11	17	21	38	89	13:1	99

11 ^aAt room temperature, asymmetric reactions involving **11** (0.50 mmol), **12** (0.55 mmol), and the
 12 polymeric catalyst (5 mol%) were conducted in 2.5 mL of CH₂Cl₂. ^bIsolated yield after purification by the
 13 column chromatography ^cEnantioselectivity (ee), as assessed by HPLC (flow rate: 1.0 mL/min on chiral
 14 cel OD-H).

15
 16 In this instance, 4-Fluoro-*trans*-nitrostyrene **15** and methyl 2-
 17 oxocyclopentanecarboxylate **11** interacted with **P2-3b** to produce Michael adducts **19**
 18 with just 72% ee. However, chiral catalyst **P2-3b** was ineffective to catalyse the reaction
 19 between malononitrile **22** with chalcone **23** and *trans*-β-nitrostyrene **12** respectively to
 20 give chiral product at room temperature. The polymeric catalysts utilised in the
 21 asymmetric reaction were easily separated and recovered from the reaction mixture by
 22 normal filtration since chiral HBPs were insoluble in frequently used organic solvent to
 23 give suspension. The recovered HBPs were applied to the same asymmetric reaction
 24 multiple times. To confirm the authenticity chiral HBP **P2-3b** used as model catalyst in

1 the asymmetric reaction in dichloromethane at room temperature. This polymer was
 2 reused up to 5 cycle to check the catalytic activity. The yield in entry 3 is higher compare
 3 to entry 2 due to the increasing of reaction time 24 to 30 h. The results of the recyclability
 4 were summarized in Table 6. Although, P2-3b catalyst maintaining the enantioselectivity
 5 and diastereoselectivity as fresh one, but decreased the yield in some extend.

6 **Table 6:** Enantioselective Michael addition^a of β -ketoesters **11** with *trans*- β -nitrostyrene **12** using
 7 different HBP P2-3a to look on recyclability performance.

Entry	Cycle	Reaction time [h]	Yield ^b [%]	<i>dr</i> ^c [%]	<i>ee</i> ^c [%]
1	fresh	24	84	8:1	>99

11 Other cinchona derived sulfonamide and ester dimers **3c**, **3d** & **3e** were prepared from
12 different cinchona derivatives and sulphonyl chloride using the same process that were
13 reported in the supporting information section.

14 **3.1.2 Synthesis of trifunctional aromatic triiodides**

15 **Synthesis of compound 9b**

16 50 mL of CH₂Cl₂ were used to mix 4, 4', 4''-Trihydroxyphenylmethane **7** (1.461 g, 5.0
17 mmol), 4-iodobenzoyl chloride **8** (4.132 g, 15.5 mmol), Et₃N (2.2 mL, 15.5 mmol), and
18 DMAP (0.20 g). At room temperature, the resulting reaction mixture was stirred
19 constantly for 4 hours. The layers were then separated after the addition of water.
20 Additional CH₂Cl₂ was used to extract the aqueous phase, and the mixed organic layer
21 was washed with brine, 10% aq. HCl solution, and 5% aq. NaOH solution before being
22 dried over anhydrous MgSO₄. The crude product was obtained after filtration and solvent
23 removal, and the chemical was then refined using silica gel column chromatography (with
24 a Hex: EtOAc = 9:1) to produce a white solid **9b** with a 48% yield. mp: 104-107 °C.

1 ¹H NMR (CDCl₃, 400 MHz, 25 °C) δ 7.86-7.91 (m, 12H), 7.15-7.21 (m, 12H), 5.63 (s,
2 1H) ppm. ¹³C NMR (100 MHz, CDCl₃, 25 °C) δ 164.6, 149.2, 141.0, 137.9, 131.4, 130.4,
3 128.9, 121.5, 101.6, 55.0 ppm.

4 5 **Synthesis of compound 9c**

6 In a 30 mL flask, 15.0 mL of CH₃CN was employed to dissolve 4,4',4''-
7 Trihydroxyphenylmethane 7 (292.34 mg, 1.0 mmol) and 4-Iodobenzyl bromide 10 (979.5
8 mg, 3.3 mmol). Cesium carbonate Cs₂CO₃ (1075.2 mg, 3.3 mmol) was then added to the
9 mixture. Under an Ar environment, the mixture was stirred at 60 °C for 18 hours. After
10 that, 60 mL of CH₂Cl₂ was filled with the reaction mixture. Yellow solid product
11 was formed and separated by filtering and evaporating the organic solution under reduced
12 pressure after it had been cleaned with water (2/30) and brine (2/30). The organic solution
13 had also been dried over anhydrous magnesium sulphate. Compound 9c was obtained
14 with a 31% yield as a white solid after the crude product was refined using silica gel (100-
15 200 mesh) column chromatography (using Hex: DCM = 1:1) R_f: 0.42 (DCM/Hex =
16 5.0/5.0). Other experimental data are found in the supporting information section.

17 18 **3.2 Synthesis of HBPs by Mizoroki-Heck polymerization reaction:**

19 **Synthesis of polymer P1-3a**

20 In a 30 mL flask, compounds **3a** (100.0 mg, 0.12674 mmol) and **9a** (104.0 mg, 0.12674
21 mmol) were combined with triethyl amine (double the amount, 35 μL, 0.2535 mmol).
22 Palladium acetate (10 mol %) and DMF solvent (3 mL) were added, and the mixture was
23 stirring at 100 °C for 48 hours. NMR was used to observe the course of the process of the
24 reaction. Then the solvent was evaporated and washed with a suitable solvent, diethyl
25 ether and finally water. The desired polymeric compounds were then dried again in a
26 vacuum oven to produce the small compound **P1-3a** as a brown solid in 79% of the cases.

1 $[\alpha]_D^{24.4} = +39.40$ (c 0.05 g/dL in DMF). ¹HNMR (400 MHz, DMSO-*d*₆, 25 °C) δ 8.68,
2 7.27-8.22 (aromatic H), 6.37-6.63 (vinylic H), 5.10, 0.61-2.92 (quinuclidine H) ppm. IR
3 (KBr) ν 3178, 3067, 2942, 2865, 1733, 1652, 1604, 1509, 1458, 1327, 1257, 1177, 1069,
4 1004, 758, 683 cm^{-1} . M_n (SEC) = 8.0×10^3 , $M_w/M_n = 1.65$.

5 Using the same procedure described in the supporting information section, additional
6 optically active hyperbranched polymers were synthesized from various sulfonamide and
7 ester dimers derived from cinchona. Table 1 summarizes the relevant results.

8 **3.3 General procedure for the asymmetric Michael addition reaction of β -** 9 **ketoesters to nitroolefins using the chiral sulfonamide polymers:**

10 *Trans*-nitrostyrene **12** (82.05 mg, 0.55 mmol) and methyl 2-oxocyclopentanecarboxylate
11 **11** (63 L, 0.50 mmol) were taken in a reaction vessel with 2.5 mL of solvent. HBPs
12 catalyst was then poured into the mixture (5 mol %). The reaction mixture was then stirred
13 for a predetermined amount of time at room temperature. A rotary evaporator was used
14 to evaporate the solvent once all **11** had been consumed (as determined by TLC). To
15 remove the utilized polymeric catalyst from the reaction mixture, the solution containing
16 the asymmetric compound was collected by pipette after being washed with ether. In
17 order to obtain the name "asymmetric compound," the solution was concentrated in vacuo
18 and the compound was purified using column chromatography on silica gel (100–200
19 mesh) with hexane/EtOAc = 6.0/1.0 as the eluent to afford the title asymmetric compound
20 as a colorless oil. ¹HNMR (400 MHz, 25 °C, CDCl₃); δ 7.29–7.23 (m, 5H), 5.14 (dd, $J =$
21 13.8 Hz, 3.8 Hz, 1H), 5.00 (dd, $J = 13.8$ Hz, 10.7 Hz, 1H), 4.08 (dd, $J = 10.8$ Hz, 3.8 Hz,
22 1H), 3.74 (s, 3H), 2.38–2.33 (m, 2H), 2.04–1.84.

23 The outcomes of further asymmetric Michael additions were carried out in a similar way,
24 and they are compiled in the Tables 2, 3, 4, 5, and 6 as well as in Scheme 5.

1 **4. Conclusion:**

2 In summary, we successfully developed novel chiral hyperbranched polymers (HPBs)
3 using the Mizoroki-Heck polymerization method, and these HPBs have a primary chain
4 repeating unit made of a sulfonamide and ester structure based on cinchona. For the chiral
5 polymerization, two components were employed as the approach. Despite the fact that
6 these chiral polymers are insoluble in commonly used organic solvents, they function as
7 a superb catalyst to the asymmetric Michael addition of ketoesters to nitroolefins,
8 resulting in up to 99% enantioselectivity and good yield. Chiral HBP **P2-3b** shows
9 excellent level of enantioselectivity (>99% *ee*) with good yield as low molecular catalyst.
10 The insoluble property give them extra space to satisfy ‘Green chemistry’ requirement
11 and used up to several times without losing enantioselectivity. Those are the HBPs
12 polymer based on sulfonamide and ester dimer of cinchona alkaloids, and successfully
13 applied on enantioselective synthesis.

14

15 **Acknowledgment:**

16 The authors would like to thank Naoki Haraguchi of the Toyohashi University of
17 Technology, for useful discussions. Financial support from the Japan International
18 Cooperation Agency (JICA) scholarship is appreciatively acknowledged.

19 **Conflicts of Interest:** The authors declare no conflict of interest.

2 [Materials and General Considerations]

3 All solvents and reagents were brought from Sigma-Aldrich, Wako Pure Chemical Industries,
4 Ltd., or Tokyo Chemical Industry (TCI) Co., Ltd. at the maximum available cleanness and were
5 used as received. Pre-coated silica gel plates (Merck 5554, 60F254) was used for Thin-layer
6 chromatography (TLC) to monitor various types of reactions progression. Column
7 chromatography was conducted by using a silica gel column (Wakogel C-200, 100–200 mesh).
8 Yanaco micro melting apparatus was used to record melting point and the average values of the
9 analysed samples were taken. NMR spectra were recorded on JEOL JNM-ECS400 spectrometers
10 and JEOL JNM-ECX500 spectrometers in CDCl₃ or DMSO-d₆ at room temperature operating at
11 400 MHz (1H), 500 MHz (1H) and 100 MHz (13C{1H}). For 1H NMR Tetramethylsilane (TMS)
12 was used as an internal standard and chemical shifts were reported in parts-per-million (ppm).
13 CDCl₃ was used as standard for 13C NMR and the J values were reported in hertz. JEOL JIR-
14 7000 Fourier transform (FT)-IR spectrometer was use to record IR spectra and reported in
15 reciprocal centimeters (cm⁻¹). High-resolution mass spectrometry (HRMS) electrospray
16 ionization (ESI) spectra were recorded using Bruker micro TOF-Q II HRMS/MS instrument.
17 High-performance liquid chromatography (HPLC) was run with a Jasco HPLC system
18 constructed of a DG-980-50 three-line degasser, a HPLC pump (PU-980), a Jasco UV-975 UV
19 detector for peak detection, and a column oven CO-2065 equipped with a chiral column
20 (Chiralpak OD-H, Daicel) with hexane/2-propanol as the eluent at a flow rate of 1.0 mL/min at
21 room temperature. Size-exclusion chromatography (SEC) was performed using a Tosoh HLC
22 8020 instrument with UV (254 nm) or refractive index detection. As a carrier solvent
23 dimethylformamide (DMF) was used at a flow rate of 1.0 mL min⁻¹ at 40 °C and two polystyrene
24 gel columns of 10-μm bead size were used. The number average molecular weight (Mn) and
25 molecular weight distribution (Mw/Mn) values were determined by using a calibration curve
26 compared with polystyrene standards. The optical rotation was obtained by using a JASCO DIP-
27 149 digital polarimeter using a 10-cm thermostatted microcell.

28 **Synthesis of cinchona derived sulfonamide and ester dimers:**

29 **Synthesis of compound 3b**

30 Cinchonidine amine **1** (1099.0 mg, 3.7456 mmol; 2 equiv or little excess), α,α'-m-xylene sulfonyl
31 chloride **2** (545.0 mg, 1.7977 mmol), triethyl amine (522 μL, 3.7456 mmol) and magnetic stir
32 bar taken in a 20 mL volumetric flask. Then dry CH₂Cl₂ 10.0 mL added to the mixture and kept
33 it at room temperature with stirring. The reaction progress was observe by TLC. After 24 hours
34 CH₂Cl₂ was removed by rotary evaporator and then the crude compound was purified by silica
35 gel (100–200 mesh) column chromatography using CH₂Cl₂: MeOH = 9:1 as an eluent to give the
36 desired compound **3b** in 48% yield as white solid. mp: 151-153 °C. $[\alpha]_D^{26.4} = -7.53$ (c 0.19 g/dL
37 in DMF). ¹NMR (400 MHz, CDCl₃, 25 °C) δ 8.95-8.92 (m, 2H), 8.23-8.28 (m, 2H), 8.10-8.12 (m,
38 2H), 7.68-7.45 (m, 2H), 7.50-7.63 (m, 4H), 7.32 (d, J=4.8, 1H), 7.02 (s, 1H), 6.83-6.92 (m, 2H),
